Moriond QCD and High Energy Interactions
9-16 March, 2013
Introduction

• Hadroproduction is studied in pp, ep, $\gamma\gamma$ collisions for 50 years
• Underlying dynamics of particle production is still not understood
• A new unified phenomenological approach is introduced
Qualitative model

Two contributions to hadron production

1. Radiation of hadrons by valence quarks
   Theses partons exist long before the interaction and considered as a thermalized statistical state
   Boltzmann-like exponential distribution

2. Virtual partons exchanged between colliding partonic systems
   power-law spectrum (typical for pQCD)

\[
\frac{d^2\sigma}{\pi dy(dp_T^2)} = A_1 \exp(-E_{T\text{kin}}/T_e) + \frac{A_2}{\left(1 + \frac{p_T^2}{T^2 N}\right)^N}
\]
Comparison of pp and $\gamma\gamma$ Spectra

$$\frac{d^2\sigma}{\pi dy (dp_T^2)} = A_1 \exp\left(-\frac{E_{T\text{kin}}}{T_e}\right) + \frac{A_2}{\left(1 + \frac{p_T^2}{T^2N}\right)^N}$$

pp-collisions have large exponential term contribution

$\gamma\gamma$-interactions are described by the power-law only
What is in ep collisions?

DIS at HERA is the unique possibility to study the change in hadroproduction dynamics

New preliminary H1 results:

1. First Measurement of charged particles spectra in DIS at $\sqrt{s} = 225$ GeV ($E_p = 460$ GeV) $\mathcal{L} = 12.45\text{pb}^{-1}$
2. High $Y$-values $0.35 < y < 0.8$
3. Low $Q^2$ $5 < Q^2 < 10$ GeV$^2$

7 $\eta^*$ bins $0 < \eta^* < 3.5$
Double differential cross-section

Central rapidity

Forward direction

Charged particle spectra $0 < \eta^* < 0.5$

Charged particle spectra $1.5 < \eta^* < 2.0$

Large exponential contribution

Small exponential contribution
The power-law term contribution decreases with approaching the proton fragmentation region as it is predicted by our model.
Conclusion

1. Qualitative model of charge particle production was introduced

2. The first measurement of DIS $d^2\sigma/dp^*T^2d\eta^*$ at $\sqrt{s} = 225$ GeV in H1 experiment was performed in seven $\eta^*$ bins.

3. The change in hadroproduction dynamics between proton and photon sides was studied.

4. Agreement between qualitative prediction of the proposed phenomenological model and experimental data was found.

Thank you for your attention!
Other predictions of the introduced model have been already tested:

1. **Exponential term is due to valence quarks**
   - Spectra in $\gamma\gamma$-collisions should have power-law term only
   - [1] Systematic studies of hadron production spectra in collider experiments

2. **QCD-fluctuations are democratic to quark flavour**
   - Kaon spectra should have less exponential distribution then pion
   - [2] Anomalous behavior of pion production in high energy particle collisions
   - [3] Comparative Analysis of Pion, Kaon and Proton Spectra Produced at PHENIX

3. **Charge multiplicity is proportional to the number of Pomerons involved**
   - Exponential contribution will decrease with the increase of multiplicity

4. **In proton fragmentation region the role of valence quarks is more important**
   - Dominance of exponential term in the high rapidity region

5. **The number of pomerons involved is increasing with the growth of the collision energy**
   - Power-law contribution will increase with the increase of $\sqrt{s}$

R Value

The relative contribution of exponential and power-law terms can be calculated by integrating each term by transverse momentum from 0 to the upper bound of the kinematical region

\[
\int_0^\infty \frac{A}{(1 + \frac{P_t^2}{T N})^N} dP_t^2 = \frac{ANT}{N - 1}
\]

\[
A_e \int_0^\infty \exp(-E_{T_{kin}}/T_e) dP_t^2 = A_e(2mT_e + 2T_e^2)
\]

\[
R = \frac{ANT}{ANT + A_e(2mT_e + 2T_e^2)(N - 1)}
\]
Monte Carlo describes the $\eta^*$ distribution rather well, but NOT the shape of the $P_T$ spectra
Why our approach is better?

Systematic defects in the data description using traditional approach

Experimental data divided over the values of the fit function in corresponding points

\[ \chi^2/\text{ndf} = 288/44 \quad \chi^2/\text{ndf} = 87/25 \]

\[ \chi^2/\text{ndf} = 54/42 \quad \chi^2/\text{ndf} = 22/23 \]

The new parameterization shows much better approximation of the experimental data.
Correlation Between Parameters

T and Te parameters in the power-law and exponential terms of the fit function are strongly correlated with each other.

\[
\frac{d^2\sigma}{\pi dy(d\rho_t^2)} = A_1\exp\left(-\frac{E_{T\text{kin}}}{T_e}\right) + \frac{A_2}{\left(1 + \frac{P_T^2}{(T^2N)}\right)^N}
\]

Better approximation is not just a result of exceeding the number of parameters of the fit function.
Expected Results for DIS

\[
\frac{d^2\sigma}{\pi dy(dp_t^2)} = A_1 \exp\left(-\frac{E_{T\text{kin}}}{T_e}\right) + \frac{A_2}{(1 + \frac{p_T^2}{T^2 N})^N}
\]
Type of produced particle

QCD-fluctuations are democratic to quark flavour while valence quark radiation can't produce heavy flavours

Prediction: Kaon (and J/ψ) spectra should have less exponential contribution then pion

\[ R = \frac{\text{Power-law}}{\text{Exp} + \text{Power-law}} \]

\( J/\psi \) spectra CDF \( \sqrt{s} = 1.96 \text{ TeV} \)
Dependence of the spectra shape on multiplicity

Charge multiplicity is proportional to the number of Pomerons involved

Prediction: Power-law contribution will increase with the increase of multiplicity

\[ R = \frac{\text{Power-law}}{\text{Exp} + \text{Power-law}} \]
Energy of Collision

The number of pomeron involved is increasing with the growth of the collision energy

Prediction: Power-law contribution will increase with the increase of $\sqrt{s}$

$$R = \frac{\text{Power-law}}{\text{Exp} + \text{Power-law}}$$
Dependence of the spectra shape on pseudorapidity

Charge particle pseudorapidity distribution at $\sqrt{s} \sim 630$ GeV

In proton fragmentation region the role of valence quarks is more important

Prediction: Dominance of exponential term in the high rapidity region

$R = \text{Power-law} + \text{Power-law}$
